blinkit

Heuristic Evaluation

I have performed a heuristic evaluation for the **Blinkit application**. It's an e- grocery app that revolutionizes the grocery buying experience.

Neilsen's Heuristic
Principles

A heuristic evaluation is a usability assessment method to identify user interface design issues.

There are 10 general principles by Jacob Nielsen for making digital things easy to use. They're called "heuristics" because they're not strict rules, but they help designers and developers create user-friendly interfaces

Visibility of system status

Match between system and the real world

User control and freedom

Consistency and standards

Error prevention

Recognition rather than recall

Flexibility and efficiency of use

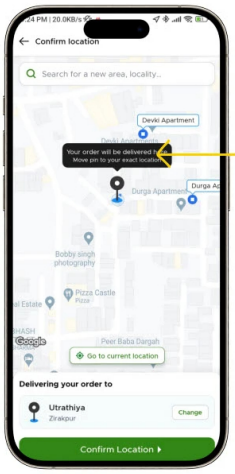

Aesthetic and minimalist design

Help users recognize, diagnose, and recover from errors

Help and documentation

Visibility of system status

"The system should always keep users informed about what is going on, through appropriate feedback within a reasonable amount of time."

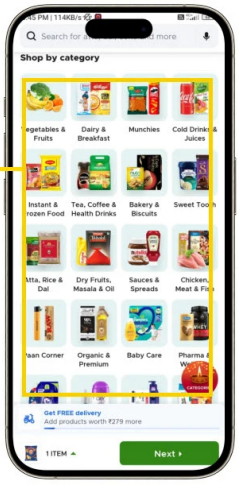

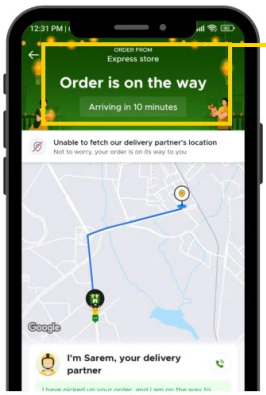

The location icon servces as an indicator of the user's current position within the app interface

Match between system and the real world

"The system should speak the users' language, with words, phrases, and concept familiar to the user, rather than system-oriented terms."

The icons used are simple and match the real world

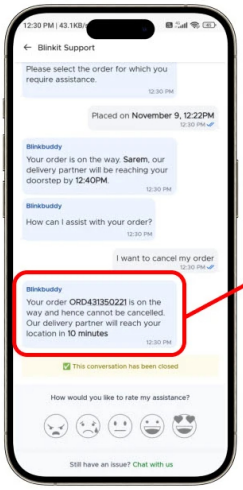

An accurate status is provided

User control and freedom

User control and freedom

"Users often needs to undo an action or get back to a previous state. Support undo and redo."

Blinkit does not offer users the ability to cancel an order even if it was processed rapidly.

Consistency and standards

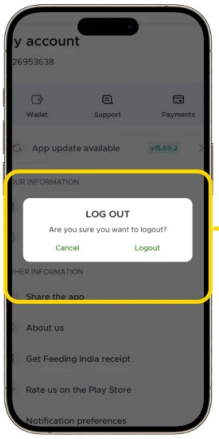

"Users should not have to wonder whether different words, situations, or actions mean the same thing."

Blinkit has followed the industry standards by placing the search bar at the top, positioning the profile view icon on the right, and maintaining a consistent typeface and color scheme across the entire application.

Error prevention

"Even better than good error messages is a careful design which prevents a problem from occurring in the first place."

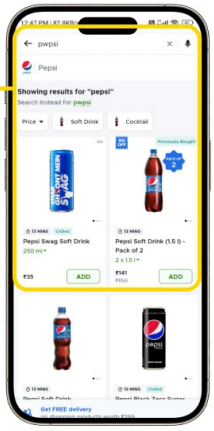

If user tap on the log out button, the system will display a pop-up message that are you sure you want to log out as seen in the Mock-Up.

Recognition rather than recall

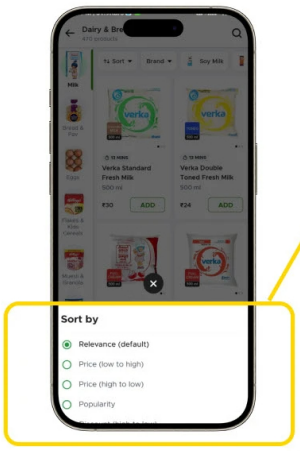

"Minimize the user's memory load by making objects, actions, and options visible."

when a user performs a search, the app delivers relevant results to speed up the process. Additionally, it offers a search history feature to help reduce cognitive load by allowing users to easily access their past searches.

Flexibility and efficiency of use

"Allow users to tailor frequent actions. Shortcuts - allows experienced users to speed up the interaction, while being unseen to novice users (new users)."

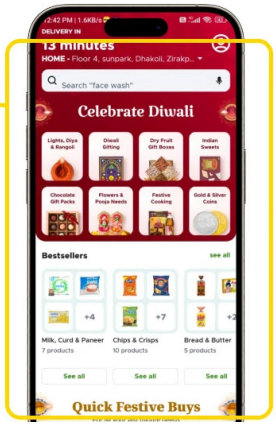

Blinkit offers users a "Filters and Categories" section when they are searching for products. This feature allows users to refine their search results and find products more efficiently.

Aesthetic and minimalist design

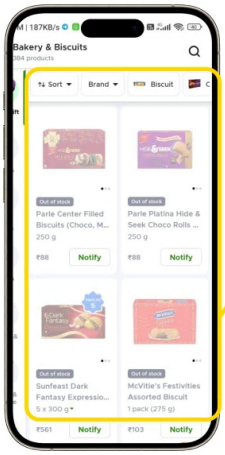

"Irrelevant information should not be included. Limit design to must have information only"

The homepage features a clean and visually appealing design. It presents essential information, such as featured products, offers, and categories, in a visually organized manner.

Help users recognize, diagnose, and recover from errors

"Error messages should be expressed in plain language (no codes), precisely indicate the problem, and constructively suggest a solution."

when a product is temporarily out of stock, the app provides users with the option to "Notify" them when the item becomes available again. This approach aids in providing a seamless and user-friendly shopping experience.

Help and documentation

"Even though it is better if the system can be used without documentation, may be necessary to provide help and documentation.

Blinkit has a chatbot to help users, but it doesn't have a FAQ section to answer the common questions. This makes it harder for users to find quick solutions on their own, which could be more convenient for them.
